```
  }

  flipState(): void {
    this.statusValue = !this.statusValue
  }

  statusValueChanged(): void {
    this.updateText()
  }

  newText(): string {
    return this.statusValue ? this.onValue : this.offValue
  }

  updateText(): void {
    this.elementWithTextTarget.innerText = this.newText()
  }
}
```

We've got three values: the status of the controller, text for when the status is "on," and text for when the status is "off." When the status changes, the "on" text is used if the status is true; otherwise, the "off" text is used. Both the text values are expected to be defined in the HTML markup as data attributes. If they aren't declared, we've given them default values.

The CSS controller is similar:

chapter_03/08/app/javascript/controllers/css_controller.ts

```
import { Controller } from "@hotwired/stimulus"

export default class CssController extends Controller {
  static classes = ["css"]
  cssClasses: string[]

  static targets = ["elementToChange"]
  elementToChangeTarget: HTMLElement

  static values = { status: Boolean }
  statusValue: boolean

  toggle(): void {
    this.flipState()
```
