`onClick` prop, which is handled normally. When the seat's status changes, the prop changes, causing the `ButtonSquare` to re-render and recompute its background color.

If the styled component is wrapping an HTML element, any known HTML attribute passed as a prop will be transparently passed along to the underlying HTML, even if you use it as a prop in defining the styled component. If the styled component is wrapping another React component, then all props will be passed through to the wrapped component.

There's also a special prop, `as`, which you'd use if you want the outermost HTML tag to be something other than as defined by styled-components. For example, our `ButtonSquare` is defined as `styled.span`, but if we wanted it to be a `div`, we could call it as `<ButtonSquare as="div">`.

There's a bit more complexity to styled-components that's outside our scope at the moment. The docs are worth checking out for how to handle more complex cases.[48]
