```
    this.firstName = firstName
    this.lastName = lastName
  }
}
```

you can use a modifier in the constructor parameter list, most commonly private, as shown here:

```
class User {
  constructor(private firstName: string, private lastName: string) {
  }
}
```

The two examples are functionally equivalent. When the constructor is called, TypeScript sets the properties of the instance based on the arguments to the constructor. TypeScript defines private, protected, public, and readonly keywords. A readonly property must either be set literally when it is declared or set in the constructor.
