```
  const text = await response.text()
  // do something with text
}
```

The `async` keyword marks the `updateData` function as having asynchronous calls within it, and therefore, able to handle the `await` keywords inside it. Within an async function, the `await` keyword expects a promise as its argument, and the code waits there until the promise resolves. In this case, a successful `fetch` returns a response wrapped in a promise, and by using `await`, the code sits in place until the response is received. Similarly, `response.text` also returns a promise, and we again `await` the response before the code flows forward.
