Frames changes the inner HTML of the frame to display the form, and then when the form is submitted, it changes the inner HTML again to display the edited concert.

Our problem is that now merely updating the inner HTML of the form submission will not trigger our sort—the sort attribute is part of the outermost DOM element. As with the favorites example, our sort controller will be sorting based on the outermost part of each concert's HTML display, which is the turbo-frame tag. So we're going to need to put the start date as a sort value on that tag, just like we did for the favorites. This was fine for the favorites, because the new favorites were being created with Turbo Streams as brand-new DOM elements all the way through. However, the form submissions are using existing Turbo Frames and only changing the text inside the turbo-frame, meaning that if we change the date of the concert in the form, any change to the sort value attribute on the outer turbo-frame itself won't get picked up and the concert won't get re-sorted.

There are a couple of ways to solve this. One way is to make the form response a Turbo Stream with a replace action rather than a Turbo Frame response. By doing so, the entire turbo-frame tag is replaced, including the outer frame itself, which means that any sort value attributes we place on the turbo-frame will also change.

To do this, we need to add one line of code to the controller method to specify a response for turbo_stream formats, much the way we did for the FavoritesController back in Chapter 2, *Hotwire and Turbo*:

chapter_10/04/app/controllers/concerts_controller.rb

```
  def update
    respond_to do |format|
      if @concert.update(concert_params)
»       format.turbo_stream {}
        format.html { render(@concert) }
        format.json { render :show, status: :ok, location: @concert }
      else
        format.html { render(:edit) }
        format.json {
```
