data only calls the reducer after the data has arrived—the waiting on ActionCable is not part of the reducer or its associated state. Our outgoing server calls as a result of user changes also happen in the React component and are not part of the reducer.

This gets a little more complicated if these dispatch calls that are associated with asynchronous server calls happen from multiple places. We either need to remember to pair the dispatch with the server call or create a wrapper around both the dispatch and the server call.
