- Set intersection returns a new set containing all elements that are in both operands. The method is intersection, and it's aliased as & .
- Set difference returns a new set with elements in the left operand that are not in the right operand. The method is difference, and it's aliased as - .
- Set xor returns a new set containing all the elements that are in exactly one of the two operands, the operator is ^ .
- You can split a set into subsets based on criteria with the classify method, which takes a block and returns a hash, the keys of which are unique values of the block and the value of the hash is every element of the set that returns the same value.

```
require "set"
d = Set[1, 2, 3, 4]
e = Set[2, 3, 4, 5]
d | e                       # => #<Set: {1, 2, 3, 4, 5}>
d.union(e)                  # => #<Set: {1, 2, 3, 4, 5}>
d & e                       # => #<Set: {2, 3, 4}>
d.intersection(e)           # => #<Set: {2, 3, 4}>
d.difference(e)             # => #<Set: {1}>
d - e                       # => #<Set: {1}>
d ^ e                       # => #<Set: {5, 1}>
d.classify { |x| x.even? } # => {false=>#<Set: {1, 3}>, true=>#<Set: {2, 4}>}
```
